1. Project Overview

Project Title: AI-Powered Email Campaign Builder for Personalized Marketing

Problem Statement:
Small business owners, creators, and marketers often struggle with creating email campaigns that are both professional and personalized. Writing email copy, formatting it for design, and planning a sequence of messages all take time and expertise that not everyone has. Current email marketing tools do not offer strong personalization or intelligent content generation based on the specific content a business wants to promote.

Objectives and Goals:

- Build an AI-powered web application that automatically creates email campaigns based on a website URL or uploaded document.
- Use natural language processing to understand the source content and generate email subject lines, body text, and calls to action.
- Enable mass personalization of emails using contact data such as names and user behavior.
- Make the system simple enough for non-technical users to create and send campaigns quickly.
- Ensure the system is fully built and deployed by the development team with no third-party AI services used for core logic.

2. Scope and Use Case

Target Audience:

- Small business owners who want to promote products or services through email.
- Content creators, freelancers, and solopreneurs who want to stay connected with their audience.
- Marketing beginners who need help generating content and running campaigns.

Use Case Scenarios:

- A business owner pastes their website URL into the app. The system reads their homepage and generates a 3-part email sequence promoting their product.
- A creator uploads a PDF eBook. The app creates follow-up emails encouraging readers to book a call or buy something related.

- A user uploads a CSV of contacts and selects a campaign goal. The system sends personalized emails to each contact with their name and behavior tags.

Project Constraints:

- Time: Limited to a six-week development cycle.
- Resources: Must use free or low-cost hosting tools like Supabase, Redis, and Azure's free tier.
- Team: Two-person development team with beginner to intermediate skill level.

3. Data Requirements

Data Sources:

- Data comes from URLs or uploaded PDFs provided by users.
- Public datasets with email templates and marketing copy styles used to train the AI components.
- Examples of email campaign language sourced from blogs, open-source email sets, and simulated marketing texts.

Data Preprocessing Needs:

- Clean website text or PDF content to remove menus, ads, and unrelated sections.
- Use tokenization to split content into useful pieces (sentences, paragraphs).
- Extract keywords, product descriptions, tone, and audience style.
- Organize training data to include examples of subject lines, CTAs, and email sequences.

Data Labeling:

- Training data is organized by type (e.g., subject line, greeting, CTA). Some labels are applied manually or generated by scripts during setup.
- Personalization variables (e.g., name, product type) are marked for later dynamic content generation.

4. Model Selection

Model Type:

- A fine-tuned transformer model will be developed for generating marketing email content.

- For content extraction, lightweight rule-based models and scraping tools will be used (BeautifulSoup, PyMuPDF).

Model Justification:

- Transformer-based models are good at understanding and generating natural language, making them ideal for creating high-quality emails.
- We chose to build and fine-tune our own small transformer model rather than using an API to ensure the project meets the build-from-scratch requirement.

Transfer Learning:

- A base transformer model will be fine-tuned using our cleaned and labeled email dataset.
- Libraries such as Hugging Face Transformers will be used in training, with our own training process and datasets.

5. Project Timeline and Milestones

Timeline:

- **Week 1:** Define scope, collect datasets, begin basic frontend and backend structure.
- **Week 2:** Implement content scraping and parsing from URLs and PDFs.
- **Week 3:** Train and test transformer model for generating subject lines and email content.
- **Week 4:** Build the backend system with FastAPI to connect model outputs to user actions.
- **Week 5:** Develop frontend interfaces for campaign building, contact management, and previewing emails.
- **Week 6:** Testing, bug fixes, deployment, and collection of user feedback.

Milestones:

- **Week 2:** Content extraction module working with input from URLs and PDFs.
- **Week 3:** Model generates emails with subject lines and body content based on input.
- **Week 5:** Frontend and backend connected for full campaign flow from input to email preview.
- **Week 6:** System is deployed and working end-to-end with personalization and scheduling.

6. Evaluation and Testing Plan

Testing Environment:

- Local testing using test URLs, PDFs, and fake contact lists.
- Full-stack integration tested in development mode on Azure.
- Final deployment tested in production on Azure App Services.

User Feedback Collection:

- App shared with classmates, instructors, and small business contacts.
- Simple feedback form included in the app for users to report issues or confusion.

Error Handling and Monitoring:

- Model prediction errors and failed email deliveries logged in Supabase.
- Alerts and logs reviewed weekly to fix bugs and improve accuracy.
- In future, error logs can be used to retrain and improve the model.

7. Ethical and Responsible AI Considerations

Data Privacy:

- No user content is stored without permission. Content is processed in memory only.
- Emails and contact data stored in encrypted format on Supabase.

Fairness and Bias:

- Model trained on diverse examples from different industries to avoid bias.
- Outputs reviewed manually during development to check for inappropriate or offensive content.
- Users can edit all generated content before sending.

Environmental Impact:

- Using pre-trained models and small datasets to reduce energy use.
- Training done on local machines or small cloud instances with efficient settings.

8. Project Outcomes and Impact

Expected Impact:

- Help small teams and individuals save time and create more professional email campaigns.
- Offer a new way to personalize emails at scale, increasing engagement and conversion.
- Allow non-marketers to compete with larger teams by using AI to automate writing and design tasks.

Future Extensions:

- Add multilingual support for international users.
- Train separate models for different industries like education, health, or real estate.
- Integrate A/B testing features to compare different email versions.
- Allow saving of custom templates and campaign histories.
